Abstract: We report the determination of phenolic compounds in olive leaves by reversed-phase HPLC/DAD, and the evaluation of their *in vitro* activity against several microorganisms that may be causal agents of human intestinal and respiratory tract infections, namely Gram positive (*Bacillus cereus*, *B. subtilis* and *Staphylococcus aureus*), Gram negative bacteria (*Pseudomonas aeruginosa*, *Escherichia coli* and *Klebsiella pneumoniae*) and fungi (*Candida albicans* and *Cryptococcus neoformans*). Seven phenolic compounds were identified and quantified: caffeic acid, verbascoside, oleuropein, luteolin 7-O-glucoside, rutin, apigenin 7-O-glucoside and luteolin 4'-O-glucoside. At low concentrations olive leaf extracts showed an unusual combined antibacterial and antifungal action, which suggests their great potential as nutraceuticals, particularly as a source of phenolic compounds.

Keywords: Olive leaves; Phenolic compounds; Antibacterial activity; Antifungal activity.

Introduction

Olive tree (*Olea europaea* L.) is one of the most important fruit trees in Mediterranean countries, where they cover 8 million ha, accounting for almost 98% of the world crop. This demonstrates the great economic and social importance of this crop and the possible benefits to be derived from utilisation of any of its byproducts [1, 2]. *Olea europaea* L. is widely studied for its alimentary use (the fruits and the oil are important components in the daily diet of a large part of the world's population), whereas the leaves are important for their secondary metabolites such as the secoiridoid compounds oleacein and oleuropein, the former responsible for hypotensive activity [3] and the latter also for hypoglycemic activity [4]. Several reports have shown that olive leaf extract has the capacity to lower blood pressure in animals [5] and increase blood flow in the coronary arteries [6], relieve arrhythmia and prevent intestinal muscle spasms [7]. Also leaves may be used in infusions, allowing a considerable intake/uptake of bioactive compounds.

Papers concerning the analysis of the phenolic components of the olive fruits, olive oil [8,9] and olive leaves [10-14] are can be found in the literature, but the investigation of those volatiles is mostly correlated to their antioxidant properties. The reports describing antimicrobial properties of phenolic compounds in olive products refer to compounds obtained from olive fruit, particularly hydroxytyrosol and oleuropein [15, 16]. A study [17] about the *in vitro* antimicrobial activity of olive leaves was reported, but the minimal inhibitory concentrations for the inhibition of microbial growth obtained were higher than in the present study. Herein, we have analysed the phenolic compounds present in olive leaves by HPLC/DAD and we evaluated the extracts antimicrobial activity against Gram positive and Gram negative bacteria and fungi.

Results and Discussion

Phenolic compounds in olive leaves

The HPLC-DAD analysis of olive leaf aqueous extract allowed the identification of seven phenolic compounds (Figure 1): caffeic acid, verbascoside, oleuropein, luteolin 7-*O*-glucoside, rutin, apigenin 7-*O*-glucoside and luteolin 4'-*O*-glucoside (Figure 2). All these compounds were previously reported to occur in olive leaf [10-14]. The quantification of the phenolics present in the aqueous extract revealed a high amount of these compounds (Table 1), that was considerably superior to the values found before for hydromethanolic extracts of the same and other olive leaf cultivars [14]. Additionally, in opposition to what happened with the hydromethanolic extracts in which flavonoids were the major compounds [14], the aqueous extract exhibited a profile in which oleuropein was the compound present in highest amount, representing ca. 73% of total identified compounds (Table 1). Caffeic acid was the minor compound, corresponding to ca. 1% of total phenolics.

The differences found in the phenolic composition are not surprising, considering that a different extractive method was applied, involving a much higher temperature, and that the present extract (aqueous) is more polar than the hydromethanolic ones analysed before [14]. On the other hand, the influence of the sample origin, in terms of both geographic provenance and year of collection, cannot be excluded.

Figure 1. HPLC phenolic profile of olive leaf lyophilized extract. Detection at (A) 280 and (B) 350 nm. (1) caffeic acid; (2) verbascoside; (3) oleuropein; (4) luteolin 7-*O*-glucoside; (5) rutin; (6) apigenin 7-*O*-glucoside; (7) luteolin 4'-*O*-glucoside.

Table 1. Quantification of the phenolic compounds in olive leaf lyophilized extract.^a

Compound	mg/kg
1 Caffeic acid	220.5 ± 23.3
2 Verbascoside	966.1 ± 18.1
3 Oleuropein	26471.4 ± 1760.2
4 Luteolin 7- <i>O</i> -glucoside	4208.9 ± 97.8
5 Rutin	495.9 ± 12.2
6 Apigenin 7- <i>O</i> -glucoside	2333.1 ± 74.7
7 Luteolin 4'- <i>O</i> -glucoside	1355.9 ± 75.9
Σ	36051.8

^a Results are expressed as mean ± standard deviation of three determinations. Σ : sum of the determined phenolic compounds. nq: not quantified.

Antimicrobial activity

As previously described, individual phenolic compounds present in the olive leaves extracts were identified and quantified, but we choose to submit the entire extracts to antimicrobial activity studies for several reasons. First, in a general way, the antimicrobial capacity of phenolic compounds is well-known [18–22]. In addition, extracts may be more beneficial than isolated constituents, since a bioactive individual component can change its properties in the presence of other compounds present in the extracts [23]. According to Liu [24] additive and synergistic effects of phytochemicals in fruits and vegetables are responsible for their potent bioactive properties and the benefit of a diet rich in fruits and vegetables is attributed to the complex mixture of phytochemicals present in whole foods. This explains why no single antimicrobial can replace the combination of natural phytochemicals to achieve the health benefits.

Olive leaf aqueous extracts were screened for their antimicrobial activity against *B. cereus*, *B. subtilis*, *S. aureus* (Gram +), *E. coli*, *P. aeruginosa*, *K. pneumoniae* (Gram -) bacteria, and *C. albicans* and *C. neoformans* (fungi). Aside from concerns with food quality degradation, these microorganisms may be causal agents of intestinal infections in humans. The extract inhibited all the tested bacteria and

fungi, suggesting a broad antimicrobial activity of olive leaf extracts in a concentration-dependent manner. According to the values of microbial growth rate in the presence of different extract concentrations, olive leaf presented antimicrobial capacity following the order *B. cereus* ~ *C. albicans* > *E. coli* > *S. aureus* > *C. neoformans* ~ *K. pneumoniae* ~ *P. aeruginosa* > *B. subtilis* (Table 2). *B. cereus* (Gram positive) and *C. albicans* (fungi) were the most sensitive microorganisms, presenting IC₂₅ values lower than 1 mg/mL. These are interesting results since 7-*O*-methylnaringenin, a known flavonoid isolated from the leaves of *Rhus retinorrhoea* Steud, Ex Olive, showed weak antimicrobial activity against *Candida albicans*, *C. krusei*, *Staphylococcus aureus*, *Mycobacterium smegmatis*, *M. intracellulare*, and *M. xenopi* [25]. *B. subtilis* was the most resistant microorganism.

The extract decreased the absorbance values at 540 nm at a concentration of 5 mg/mL, indicating inhibition of bacterial (Figure 3) and fungal growth (Figure 4), relative to the control (without extract) after 24h and 48 h of incubation, respectively. Certainly the chemical composition of olive leaf extracts conditioned the antimicrobial effects observed. The high content of oleuropein and the other phenolic compounds identified in the extract might contribute for its antimicrobial properties.

Hydroxytyrosol and oleuropein are other phenolic compounds that have been proven to inhibit or delay the rate of growth of several human intestinal or respiratory tract pathogens, namely *Haemophilus influenzae*, *Moraxella catarrhalis*, *Salmonella typhi*, *Vibrio parahaemolyticus*, *Staphylococcus aureus*, *Vibrio cholerae* and *Vibrio alginolyticus* [15].

The unusual combined antibacterial and antifungal action obtained in this study for olive leaf extracts is in agreement with that reported by Markin *et al.* [17]. Nevertheless, we obtained lower IC₂₅ values than the 0.6% described by them. Olive leaves may be useful in cases where prolonged use of antibiotics encourage development of opportunistic infections [26], being especially effective against *Klebsiella* and *Pseudomonas*, two bacterial genera which pose a major resistance problem [27].

In conclusion, the data obtained in this study demonstrate that the use of olive leaves as nutraceuticals may lower the risk of microbial infections, particularly in the intestinal and respiratory tract, mainly due to the protective action provided by its phenolic compounds. The use of extracts is recommended to achieve health benefits due to the additive and synergistic effects of phytochemicals present in whole extract.

Figure 4. Fungal growth in the presence of olive leaves extract (5 mg/mL) and in the absence of extract (0 mg/mL) along the incubation period (48 h).

Experimental

Samples

Olive leaves samples of Cv. Cobrançosa were collected in November 2004 in an olive grove located in Trás-os-Montes, Northeast Portugal. The orchard has a planting density of 7×7 m. The trees have twelve years old, being pruned when necessary, not irrigated and no phytosanitary treatments had been applied in the last year. The leaves were collected at the operator height around the whole perimeter of each tree. The collected samples were put in plastic bags and immediately frozen at -20°C . The plant material was then freeze dried and powdered (20 mesh).

Identification and quantification of phenolic compounds

Standards and reagents. The standards used were from Sigma (St. Louis, MO, USA) or Extrasynthèse (Genay, France). Methanol and formic acid were obtained from Merck (Darmstadt, Germany). The water was treated in a Milli-Q water purification system (Millipore, Bedford, MA, USA) before use.

Extraction of phenolic compounds. An aqueous extract of olive leaves was prepared by putting dried material (ca. 5.0 g) in boiling water (150 mL). The mixture was boiled for 30 min and then filtered over a Büchner funnel. The obtained extract was then lyophilised. The lyophilised extract was kept in an exsicator, in the dark. For phenolic compounds analysis it was redissolved in water.

HPLC-DAD system for analysis of phenolic compounds. Chromatographic separation was achieved as previously reported [14] with an analytical HPLC unit (Gilson) coupled to a diode array detector (DAD) (Gilson), using a reversed-phase Spherisorb ODS2 (250 x 4.6 mm, 5 μm particle size, Merck, Darmstadt, Germany) column. The solvent system used was a gradient of water/formic acid (19:1) (A) and methanol (B), starting with 15% methanol and installing a gradient to obtain 18%B at 3 min, 25%B at 6 min, 39%B at 19 min, 39%B at 22 min, 50%B at 36 min, 79%B at 59 min and 100%B at 60 min. The flow rate was 0.9 mL/min, and the injection volume was 20 μL . Chromatograms were recorded at 280, 320 and 350 nm. Spectral data from all peaks were accumulated in the 200–400 nm range. Data were processed on a Unipoint system software (Gilson Medical Electronics, Villiers le Bel, France). Phenolic compound quantification was achieved by the absorbance recorded in the chromatograms relative to external standards, with detection at 280 nm for oleuropein, at 320 nm for caffeic acid and verbascoside and at 350 nm for flavonoids. Luteolin derivatives were quantified as luteolin 7-O-glucoside. The other compounds were quantified as themselves.

Antimicrobial Activity

Extract preparation. Powdered sample (5 g) was extracted with boiling water (250 mL) for 45 min and filtered through Whatman n°4 paper. The aqueous extract was frozen, lyophilized and redissolved in water at a concentration of 50 mg/mL, and analysed for their antimicrobial activity.

Microorganisms and culture conditions. The bacterial strains used were *Bacillus cereus* CECT 148, *B. subtilis* CECT 498, *Staphylococcus aureus* ESA 7, *Escherichia coli* CECT 101, *Pseudomonas aeruginosa* CECT 108, and *Klebsiella pneumoniae* ESA 8. The fungi strains used were *Candida albicans* CECT 1394 and *Cryptococcus neoformans* ESA 3. Microorganisms CECT were obtained from the Spanish type culture collection (CECT) of Valencia University, while microorganisms ESA were clinically isolated strains identified in Microbiology Laboratory of Escola Superior Agrária de Bragança. Microorganisms were cultured aerobically at 37 °C in nutrient agar medium for bacteria, and at 30 °C (Scientific 222 oven model, 2003) in Sabouraud dextrose agar medium for fungi. Before experimental use, cultures from solid medium were subcultivated in liquid media, incubated and used as the source of inoculums for each experiment.

Test assays for antibacterial activity. A macro-broth-dilution technique [38] was used to determine the growth inhibition of the susceptible Gram + (*B. subtilis*, *B. cereus*, *S. aureus*) and Gram – (*E. coli*, *K. pneumoniae*) bacteria, and fungi (*C. albicans*, *C. neoformans*) to olive leaves. A nutrient medium (10 g tryptone, 5 g meat extract, water to 1 L) was used to prepare the inocula after being sterilized in an autoclave (P Selecta model, 2002) at 121 °C for 20 min). Erlenmeyer flasks (50 mL) containing the liquid culture medium (10 mL) were inoculated with the bacteria suspension (10^8 cfu/mL) and each extract concentration to be tested (0.05–5 mg/mL) was added. Incubation was carried out for 24 hours at 37 °C in a rotary shaker (Stuart Scientific SI50 model, 2001) at 150 rpm. The growth of bacteria cultures was monitored by measuring optical density at 540 nm in a UV–visible spectrophotometer (Varian Cary 50 Scan model, 1998). Controls were carried out in the same conditions but in the absence of sample extract. All assays were carried out under aseptic conditions. Values for bacteria growth rate were obtained by linear regression analysis in the exponential growth range in the graphs of optical density at 540 nm versus incubation time. The equation curve slope was considered the rate of microbial growth. IC₂₅ values (extract concentration which inhibits 25% of microbial growth) were also determinate.
